

Recursion

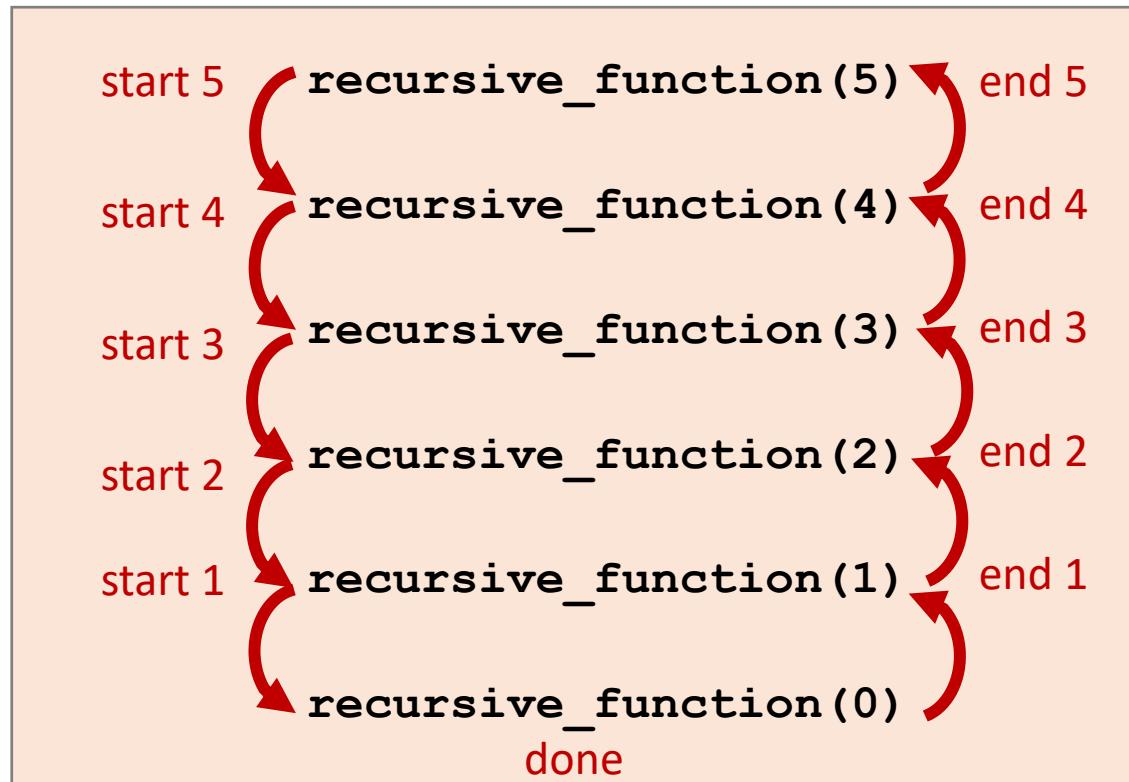

- symbol table
- stack frames

Recursion

Recursive function

=

"function that calls itself"

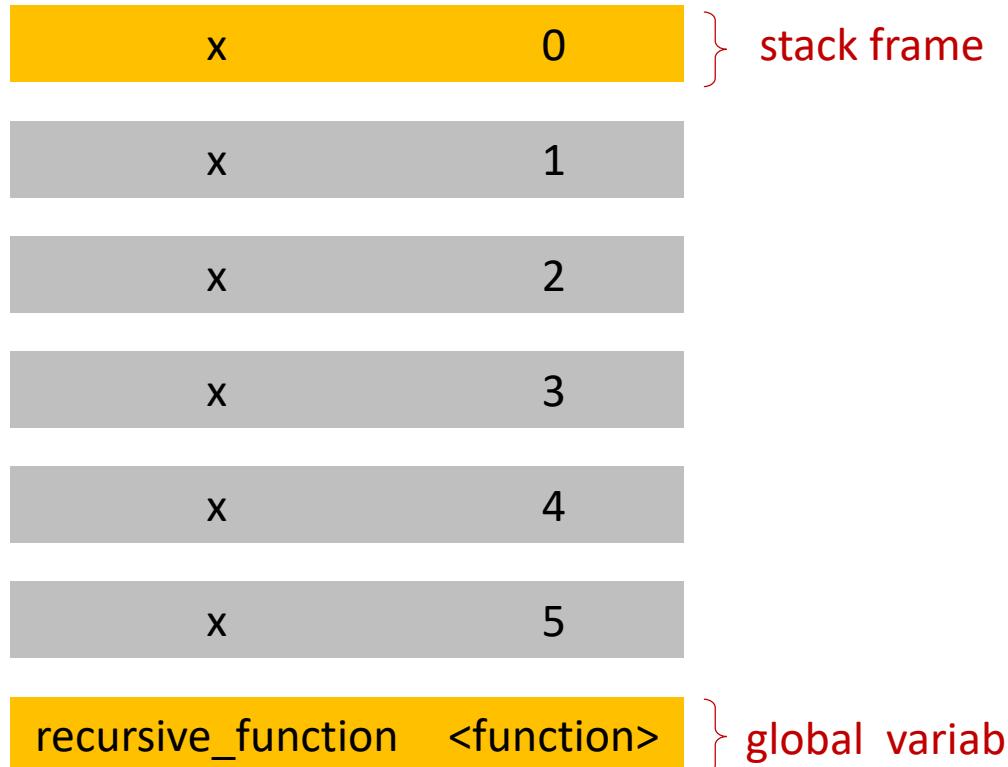

Python shell

```
> def recursive_function(x):
    if x > 0:
        print("start", x)
        recursive_function(x - 1)
        print("end", x)
    else:
        print("done")
```

```
> recursive_function(5)
```

```
| start 5
| start 4
| start 3
| start 2
| start 1
| done
| end 1
| end 2
| end 3
| end 4
| end 5
```

Recursion

Recursions stack when $x = 0$ is reached

Python shell

```
> def recursive_function(x):
    if x > 0:
        print("start", x)
        recursive_function(x - 1)
        print("end", x)
    else:
        print("done")
```

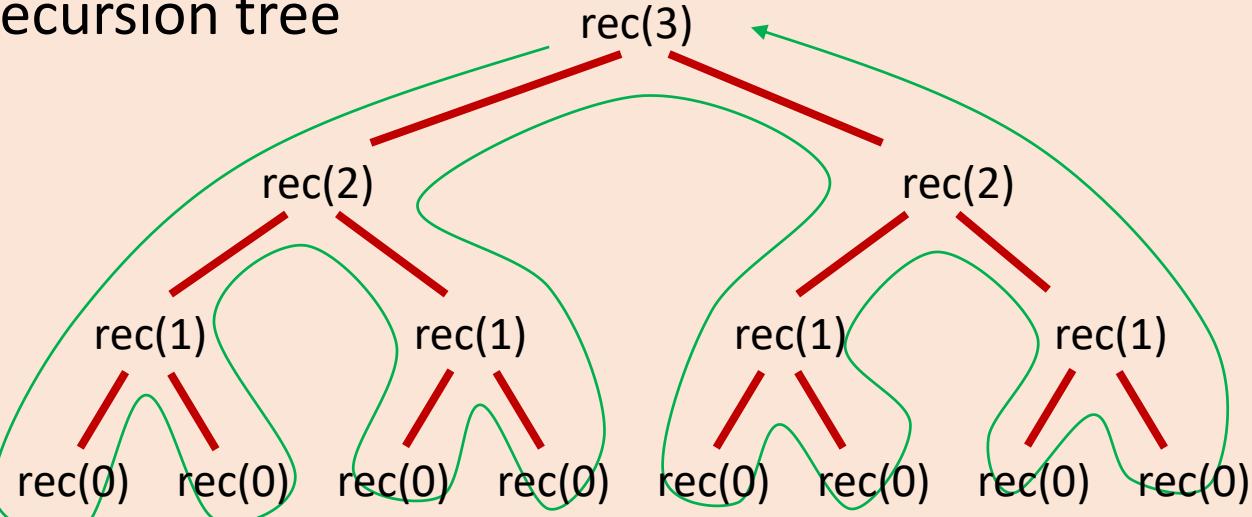

```
> recursive_function(5)
```

```
| start 5
| start 4
| start 3
| start 2
| start 1
| done
| end 1
| end 2
| end 3
| end 4
| end 5
```

Python shell

```
> def rec(x):
    if x > 0:
        print("start", x)
        rec(x - 1)
        rec(x - 1)
        print("end", x)
    else:
        print("done")
```

Recursion tree

Python shell

```
> rec(3)
| start 3
| start 2
| start 1
| done
| done
| end 1
| start 1
| done
| done
| end 1
| end 2
| start 2
| start 1
| done
| done
| end 1
| start 1
| done
| done
| end 1
| end 2
| end 3
```

Question – How many times does `rec(5)` print “done”?

Python shell

```
> def rec(x):
    if x > 0:
        print("start", x)
        rec(x - 1)
        rec(x - 1)
        rec(x - 1)
        print("end", x)
    else:
        print("done")
```

- a) 3
- b) 5
- c) 15
- d) 81
- e) 125
-  f) 243
- g) Don't know

Factorial

$$n! = n \cdot \underbrace{(n-1) \cdot (n-2) \cdots 3 \cdot 2 \cdot 1}_{(n-1)!}$$

Observation
(recursive definition)

$$\begin{aligned}1! &= 1 \\n! &= n \cdot (n-1)!\end{aligned}$$

factorial.py

```
def factorial(n):
    if n <= 1:
        return 1
    return n * factorial(n - 1)
```

factorial.py

```
def factorial(n):
    return n * factorial(n - 1) if n > 1 else 1
```

factorial_iterative.py

```
def factorial(n):
    result = 1
    for i in range(2, n + 1):
        result *= i
    return result
```

Binomial coefficient $\binom{n}{k}$

- $\binom{n}{k}$ = number of ways to pick k elements from a set of size n
- $$\binom{n}{k} = \begin{cases} 1 & \text{if } k = 0 \text{ or } k = n \\ \binom{n-1}{k} + \binom{n-1}{k-1} & \text{otherwise} \end{cases}$$

bionomial_recursive.py

```
def binomial(n, k):  
    if k == 0 or k == n:  
        return 1  
    return binomial(n - 1, k) + binomial(n - 1, k - 1)
```

- Unfolding computation shows $\binom{n}{k}$ 1's are added → slow

Binomial coefficient $\binom{n}{k}$

Observation $\binom{n}{k} = \frac{n !}{(n - k) ! \cdot k !}$

```
bionomial_factorial.py
```

```
def binomial(n, k):
    return factorial(n) // factorial(k) // factorial(n - k)
```

- Unfolding computation shows $2n - 2$ multiplications and 2 divisions → **fast**
- Intermediate value $n !$ can have significantly more digits than result (**bad**)

Binomial coefficient $\binom{n}{k}$

Observation
$$\binom{n}{k} = \frac{n \cdot (n - 1) \cdot (n - 2) \cdots (n - k + 1)}{k \cdot (k - 1) \cdot (k - 2) \cdots 1} = \binom{n - 1}{k - 1} \cdot \frac{n}{k}$$

bionomial_recursive_product.py

```
def binomial(n, k):
    if k == 0:
        return 1
    else:
        return binomial(n - 1, k - 1) * n // k
```

- Unfolding computation shows $2k - 2$ multiplications and k divisions → fast
- Multiplication with fractions ≥ 1 → intermediate numbers limited size

Questions – Which correctly computes $\binom{n}{k}$?

Observation $\binom{n}{k} = \frac{n \cdot (n - 1) \cdot (n - 2) \cdots (n - k + 1)}{k \cdot (k - 1) \cdot (k - 2) \cdots 1}$

- a) binomial_A
-  b) binomial_B
- c) both
- d) none
- e) Don't know

bionomial_iterative.py

```
def binomial_A(n, k):
    result = 1
    for i in range(k):
        result = result * (n - i) // (k - i)
    return result

def binomial_B(n, k):
    result = 1
    for i in range(k)[::-1]:
        result = result * (n - i) // (k - i)
    return result
```

Recursively print all leaves of a tree

- Assume a recursively nested tuple represents a tree with strings as leaves

Python shell

```
> def print_leaves(tree):
    if isinstance(tree, str):
        print("Leaf:", tree)
    else:
        for child in tree:
            print_leaves(child)

> print_leaves(('a', ('b', 'c')))
| Leaf: a
| Leaf: b
| Leaf: c
```

Question – How many times is `print_leaves` function called in the example?

Python shell

```
> def print_leaves(tree):
    if isinstance(tree, str):
        print("Leaf:", tree)
    else:
        for child in tree:
            print_leaves(child)

> print_leaves([('a', ('b', 'c')))
| Leaf: a
| Leaf: b
| Leaf: c
```

- a) 3
- b) 4
-  c) 5
- d) 6
- e) Don't know

Collect all leaves of a tree in a set

Python shell

```
> def collect_leaves_slow(tree):
    leaves = set()
    if isinstance(tree, str):
        leaves.add(tree)
    else:
        for child in tree:
            leaves |= collect_leaves_slow(child)
    return leaves

> collect_leaves_slow([('a', ('b', 'c'))))
| {'a', 'c', 'b'}
```

copies all labels from child from one set to another set

Python shell

```
> def collect_leaves_wrong(tree, leaves = set()):  
    if isinstance(tree, str):  
        leaves.add(tree)  
    else:  
        for child in tree:  
            collect_leaves_wrong(child, leaves)  
return leaves  
  
> def collect_leaves_right(tree, leaves = None):  
    if leaves == None:  
        leaves = set()  
    if isinstance(tree, str):  
        leaves.add(tree)  
    else:  
        for child in tree:  
            collect_leaves_right(child, leaves)  
return leaves
```

```
> collect_leaves_wrong(('a',('b','c')))  
| {'a', 'c', 'b'}  
> collect_leaves_wrong(('d',('e','f')))  
| {'b', 'e', 'a', 'f', 'c', 'd'}  
  
> collect_leaves_right(('a',('b','c')))  
| {'b', 'a', 'c'}  
> collect_leaves_right(('d',('e','f')))  
| {'f', 'd', 'e'}
```

Python shell

```
> def collect_leaves(tree):
    leaves = set()

    def traverse(tree):
        nonlocal leaves # can be omitted
        if isinstance(tree, str):
            leaves.add(tree)
        else:
            for child in tree:
                traverse(child)

    traverse(tree)
    return leaves

> collect_leaves([('a', ('b', 'c')))
| {'b', 'a', 'c'}
> collect_leaves([('d', ('e', 'f'))))
| {'f', 'd', 'e'}
```

Maximum recursion depth ?

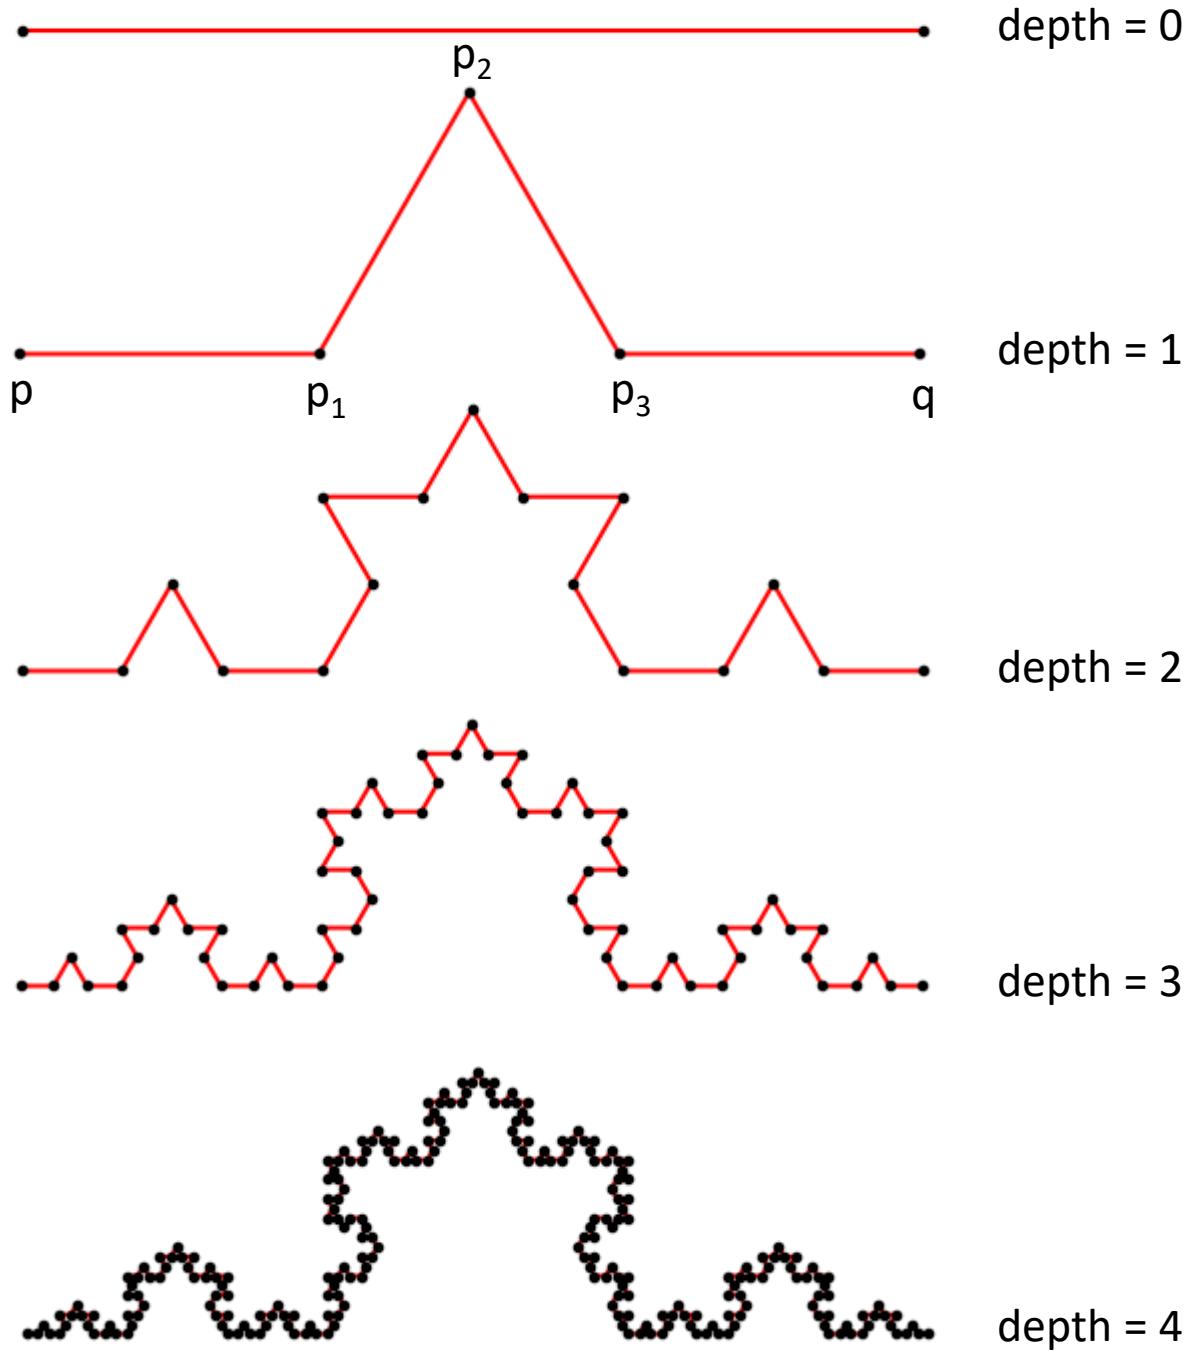

- Pythons maximum allowed recursion depth can be increased by

```
import sys  
sys.setrecursionlimit(1500)
```

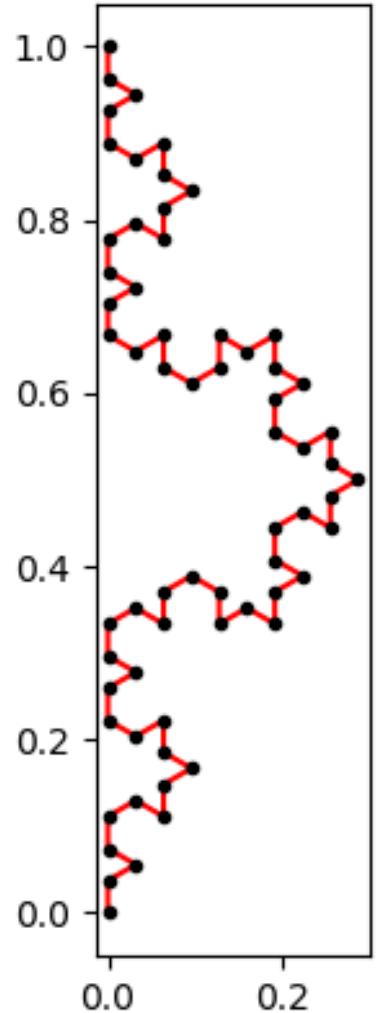

Python shell

```
> def f(x):  
    print("#", x)  
    f(x + 1)  
  
> f(1)  
# 1  
# 2  
# 3  
...  
# 975  
# 976  
# 977  
# 978  
RecursionError: maximum  
recursion depth exceeded  
while pickling an object
```

Koch Curves

Koch Curves

koch_curve.py

```
import matplotlib.pyplot as plt
from math import sqrt

def koch(p, q, depth=3):
    if depth == 0:
        return [p, q]

    dx, dy = q[0] - p[0], q[1] - p[1]
    h = 1 / sqrt(12)
    p1 = p[0] + dx / 3, p[1] + dy / 3
    p2 = p[0] + dx / 2 - h * dy, p[1] + dy / 2 + h * dx
    p3 = p[0] + dx * 2 / 3, p[1] + dy * 2 / 3
    return (koch(p, p1, depth - 1)[:-1]
            + koch(p1, p2, depth - 1)[:-1]
            + koch(p2, p3, depth - 1)[:-1]
            + koch(p3, q, depth - 1))

points = koch((0, 1), (0, 0), depth=3)
x, Y = zip(*points)
plt.subplot(aspect='equal')
plt.plot(x, Y, 'r-')
plt.plot(x, Y, 'k.')
plt.show()
```

remove last point
(equal to first point in
next recursive call)
